

# Codeforces Round #345 (Div. 1)

## A. Watchmen

time limit per test: 3 seconds

memory limit per test: 256 megabytes

input: standard input

output: standard output

Watchmen are in a danger and Doctor Manhattan together with his friend Daniel Dreiberg should warn them as soon as possible. There are  $n$  watchmen on a plane, the  $i$ -th watchman is located at point  $(x_i, y_i)$ .

They need to arrange a plan, but there are some difficulties on their way. As you know, Doctor Manhattan considers the distance between watchmen  $i$  and  $j$  to be  $|x_i - x_j| + |y_i - y_j|$ . Daniel, as an ordinary person, calculates the distance using the formula .

The success of the operation relies on the number of pairs  $(i, j)$  ( $1 \leq i < j \leq n$ ), such that the distance between watchman  $i$  and watchmen  $j$  calculated by Doctor Manhattan is equal to the distance between them calculated by Daniel. You were asked to compute the number of such pairs.

### Input

The first line of the input contains the single integer  $n$  ( $1 \leq n \leq 200\,000$ ) — the number of watchmen.

Each of the following  $n$  lines contains two integers  $x_i$  and  $y_i$  ( $|x_i|, |y_i| \leq 10^9$ ).

Some positions may coincide.

### Output

Print the number of pairs of watchmen such that the distance between them calculated by Doctor Manhattan is equal to the distance calculated by Daniel.

### Examples

input
3 1 1 7 5 1 5
output
2
input
6 0 0 0 1 0 2 -1 1 0 1 1 1
output
11

### Note

In the first sample, the distance between watchman 1 and watchman 2 is equal to  $|1 - 7| + |1 - 5| = 10$  for Doctor Manhattan and for Daniel. For pairs (1, 1), (1, 5) and (7, 5), (1, 5) Doctor Manhattan and Daniel will calculate the same distances.

## B. Image Preview

time limit per test: 1 second

memory limit per test: 256 megabytes

input: standard input

output: standard output

Vasya's telephone contains  $n$  photos. Photo number 1 is currently opened on the phone. It is allowed to move left and right to the adjacent photo by swiping finger over the screen. If you swipe left from the first photo, you reach photo  $n$ . Similarly, by swiping right from the last photo you reach photo 1. It takes  $a$  seconds to swipe from photo to adjacent.

For each photo it is known which orientation is intended for it — horizontal or vertical. Phone is in the vertical orientation and **can't** be rotated. It takes  $b$  second to change orientation of the photo.

Vasya has  $T$  seconds to watch photos. He want to watch as many photos as possible. If Vasya opens the photo for the first time, he spends 1 second to notice all details in it. If photo is in the wrong orientation, he spends  $b$  seconds on rotating it before watching it. If Vasya has already opened the photo, he just skips it (so he doesn't spend any time for watching it or for changing its orientation). It is not allowed to skip unseen photos.

Help Vasya find the maximum number of photos he is able to watch during  $T$  seconds.

### Input

The first line of the input contains 4 integers  $n, a, b, T$  ( $1 \leq n \leq 5 \cdot 10^5$ ,  $1 \leq a, b \leq 1000$ ,  $1 \leq T \leq 10^9$ ) — the number of photos, time to move from a photo to adjacent, time to change orientation of a photo and time Vasya can spend for watching photo.

Second line of the input contains a string of length  $n$  containing symbols 'w' and 'h'.

If the  $i$ -th position of a string contains 'w', then the photo  $i$  should be seen in the **horizontal** orientation.

If the  $i$ -th position of a string contains 'h', then the photo  $i$  should be seen in **vertical** orientation.

### Output

Output the only integer, the maximum number of photos Vasya is able to watch during those  $T$  seconds.

### Examples

input
4 2 3 10 wwhw
output
2
input
5 2 4 13 hhwhh
output
4
input
5 2 4 1000 hhwhh
output
5
input
3 1 100 10 whw
output
0

### Note

In the first sample test you can rotate the first photo (3 seconds), watch the first photo (1 seconds), move left (2 second), rotate fourth photo (3 seconds), watch fourth photo (1 second). The whole process takes exactly 10 seconds.

Note that in the last sample test the time is not enough even to watch the first photo, also you can't skip it.

## C. Table Compression

time limit per test: 4 seconds  
memory limit per test: 256 megabytes  
input: standard input  
output: standard output

Little Petya is now fond of data compression algorithms. He has already studied *gz*, *bz*, *zip* algorithms and many others. Inspired by the new knowledge, Petya is now developing the new compression algorithm which he wants to name *dis*.

Petya decided to compress tables. He is given a table  $a$  consisting of  $n$  rows and  $m$  columns that is filled with positive integers. He wants to build the table  $a'$  consisting of positive integers such that the relative order of the elements in each row and each column remains the same. That is, if in some row  $i$  of the initial table  $a_{i,j} < a_{i,k}$ , then in the resulting table  $a'_{i,j} < a'_{i,k}$ , and if  $a_{i,j} = a_{i,k}$  then  $a'_{i,j} = a'_{i,k}$ . Similarly, if in some column  $j$  of the initial table  $a_{i,j} < a_{p,j}$  then in compressed table  $a'_{i,j} < a'_{p,j}$  and if  $a_{i,j} = a_{p,j}$  then  $a'_{i,j} = a'_{p,j}$ .

Because large values require more space to store them, the maximum value in  $a'$  should be as small as possible.

Petya is good in theory, however, he needs your help to implement the algorithm.

### Input

The first line of the input contains two integers  $n$  and  $m$  (, the number of rows and the number of columns of the table respectively).

Each of the following  $n$  rows contain  $m$  integers  $a_{i,j}$  ( $1 \leq a_{i,j} \leq 10^9$ ) that are the values in the table.

### Output

Output the compressed table in form of  $n$  lines each containing  $m$  integers.

If there exist several answers such that the maximum number in the compressed table is minimum possible, you are allowed to output any of them.

### Examples

input
2 2 1 2 3 4
output
1 2 2 3

input
4 3 20 10 30 50 40 30 50 60 70 90 80 70
output
2 1 3 5 4 3 5 6 7 9 8 7

### Note

In the first sample test, despite the fact  $a_{1,2} \neq a_{2,1}$ , they are not located in the same row or column so they may become equal after the compression.

## D. Zip-line

time limit per test: 3 seconds

memory limit per test: 256 megabytes

input: standard input

output: standard output

Vasya has decided to build a zip-line on trees of a nearby forest. He wants the line to be as long as possible but he doesn't remember exactly the heights of all trees in the forest. He is sure that he remembers correct heights of all trees except, possibly, one of them.

It is known that the forest consists of  $n$  trees staying in a row numbered from left to right with integers from 1 to  $n$ . According to Vasya, the height of the  $i$ -th tree is equal to  $h_i$ . The zip-line of length  $k$  should hang over  $k$  ( $1 \leq k \leq n$ ) trees  $i_1, i_2, \dots, i_k$  ( $i_1 < i_2 < \dots < i_k$ ) such that their heights form an increasing sequence, that is  $h_{i_1} < h_{i_2} < \dots < h_{i_k}$ .

Petya had been in this forest together with Vasya, and he now has  $q$  assumptions about the mistake in Vasya's sequence  $h$ . His  $i$ -th assumption consists of two integers  $a_i$  and  $b_i$  indicating that, according to Petya, the height of the tree numbered  $a_i$  is actually equal to  $b_i$ . Note that Petya's assumptions are **independent** from each other.

Your task is to find the maximum length of a zip-line that can be built over the trees under each of the  $q$  assumptions.

In this problem the length of a zip line is considered equal to the number of trees that form this zip-line.

### Input

The first line of the input contains two integers  $n$  and  $m$  ( $1 \leq n, m \leq 400\,000$ ) — the number of the trees in the forest and the number of Petya's assumptions, respectively.

The following line contains  $n$  integers  $h_i$  ( $1 \leq h_i \leq 10^9$ ) — the heights of trees according to Vasya.

Each of the following  $m$  lines contains two integers  $a_i$  and  $b_i$  ( $1 \leq a_i \leq n, 1 \leq b_i \leq 10^9$ ).

### Output

For each of the Petya's assumptions output one integer, indicating the maximum length of a zip-line that can be built under this assumption.

### Examples

input
4 4 1 2 3 4 1 1 1 4 4 3 4 5
output
4 3 3 4

  

input
4 2 1 3 2 6 3 5 2 4
output
4 3

### Note

Consider the first sample. The first assumption actually coincides with the height remembered by Vasya. In the second assumption the heights of the trees are (4, 2, 3, 4), in the third one they are (1, 2, 3, 3) and in the fourth one they are (1, 2, 3, 5).

## E. Clockwork Bomb

time limit per test: 6 seconds  
memory limit per test: 256 megabytes  
input: standard input  
output: standard output

My name is James diGriz, I'm the most clever robber and treasure hunter in the whole galaxy. There are books written about my adventures and songs about my operations, though you were able to catch me up in a pretty awkward moment.

I was able to hide from cameras, outsmart all the guards and pass numerous traps, but when I finally reached the treasure box and opened it, I have accidentally started the clockwork bomb! Luckily, I have met such kind of bombs before and I know that the clockwork mechanism can be stopped by connecting contacts with wires on the control panel of the bomb in a certain manner.

I see  $n$  contacts connected by  $n - 1$  wires. Contacts are numbered with integers from  $1$  to  $n$ . Bomb has a security mechanism that ensures the following condition: if there exist  $k \geq 2$  contacts  $c_1, c_2, \dots, c_k$  forming a circuit, i. e. there exist  $k$  **distinct** wires between contacts  $c_1$  and  $c_2$ ,  $c_2$  and  $c_3$ , ...,  $c_k$  and  $c_1$ , then the bomb immediately explodes and my story ends here. In particular, if two contacts are connected by more than one wire they form a circuit of length  $2$ . It is also prohibited to connect a contact with itself.

On the other hand, if I disconnect more than one wire (i. e. at some moment there will be no more than  $n - 2$  wires in the scheme) then the other security check fails and the bomb also explodes. So, the only thing I can do is to unplug some wire and plug it into a new place ensuring the fact that no circuits appear.

I know how I should put the wires in order to stop the clockwork. But my time is running out! Help me get out of this alive: find the sequence of operations each of which consists of unplugging some wire and putting it into another place so that the bomb is defused.

### Input

The first line of the input contains  $n$  ( $2 \leq n \leq 500\,000$ ), the number of contacts.

Each of the following  $n - 1$  lines contains two of integers  $x_i$  and  $y_i$  ( $1 \leq x_i, y_i \leq n, x_i \neq y_i$ ) denoting the contacts currently connected by the  $i$ -th wire.

The remaining  $n - 1$  lines contain the description of the sought scheme in the same format.

It is guaranteed that the starting and the ending schemes are correct (i. e. do not contain circuits nor wires connecting contact with itself).

### Output

The first line should contain  $k$  ( $k \geq 0$ ) — the minimum number of moves of unplugging and plugging back some wire required to defuse the bomb.

In each of the following  $k$  lines output four integers  $a_i, b_i, c_i, d_i$  meaning that on the  $i$ -th step it is necessary to unplug the wire connecting the contacts  $a_i$  and  $b_i$  and plug it to the contacts  $c_i$  and  $d_i$ . Of course the wire connecting contacts  $a_i$  and  $b_i$  should be present in the scheme.

If there is no correct sequence transforming the existing scheme into the sought one, output  $-1$ .

### Examples

input
3 1 2 2 3 1 3 3 2
output
1 1 2 1 3

  

input
4 1 2 2 3 3 4 2 4 4 1 1 3
output
3 1 2 1 3 4 3 4 1 2 3 2 4
